Data sharing for prevention: a case study in the development of a comprehensive emergency department injury surveillance system and its use in preventing violence and alcohol-related harms

Zara Quigg, Karen Hughes, Mark A Bellis

ABSTRACT

Objective To examine emergency department (ED) data sharing via a local injury surveillance system and assess its contribution to the prevention of violence and alcohol-related harms.

Results Over the 6-year period, there were 242,796 ED injury attendances, including 21,683 for intentional injuries. Compared with unintentional injury patients, intentional injury patients were more likely to be men, aged 18–34 years, live in the most deprived communities, have attended the ED at night/weekends, have been injured in a public place and have consumed alcohol prior to the injury. Detailed data collected on alcohol and violence-related ED attendances were shared with local partners to monitor local trends and inform prevention activity including targeted policing and licensing enforcement. Over the 6-year period, intentional ED injury attendances decreased by 35.6% and alcohol-related assault attendances decreased by 30.3%.

Conclusions The collection of additional ED data on assault details and alcohol use prior to injury, and its integration into multi-agency policy and practice, played an important role in driving local violence prevention activity. Further research is needed to assess the direct contribution ED data sharing makes to reductions in violence.

INTRODUCTION

The WHO promotes the sharing and use of emergency department (ED) data as a major component in the public health approach to prevent injuries.1–3 Routine recording of attendance cause and patient demographics means ED data can be used to monitor injuries, identify ‘at risk groups and communities’ for targeting appropriate prevention activity and evaluate its impacts. Injury surveillance systems (ISSs) using data captured in EDs have been successfully established in both high and middle income countries.4–9 However, in many countries the use of ED data for injury prevention remains underdeveloped.8 10

In the UK, a range of ED-based ISSs have been established to inform injury prevention. With some exceptions (eg, All Wales ISS11), most have focused on specific injury types,12 injury severity13 or age groups.14 In England, a national commissioning dataset (NCD)15 has been established that requires all EDs to collect a standard set of data on individual attendances, including injury group and location, patient demographics, attendance time and date, and arrival, referral and disposal method. These data were first published in 2009 and are updated annually. However, data are currently incomplete, of poor quality and not available at a suitable level for use in local injury prevention work.16 There is growing recognition across the UK of the utility of ED data in injury prevention. In particular, the government is promoting the collection of detailed data on violence and its sharing with police and other agencies to target violence prevention.17 In 2009, the College of Emergency Medicine published guidelines for EDs to support information sharing to reduce violence.18 Despite the increasing support for ED data sharing, local partners have struggled to access data.19 Factors including variations in data collection methods and information systems between EDs, poor understanding of what can be shared while maintaining patient confidentiality and a lack of incentives for health services to share data have hampered data sharing.19 20

In 2002, the Trauma and Injury Intelligence Group (TIIG) multi-agency ISS (box 1) was established to improve the availability and use of injury data in the English county of Merseyside, with a particular focus on ED data. Since its inception, TIIG has expanded to cover all 31 EDs (across 39 local authority areas) in the North West of England. TIIG offers a comprehensive ED ISS that covers all injury types, all population groups and operates flexibly to meet the needs of local partners. In this article, we describe the establishment of TIIG in Wirral local authority area. Wirral’s single ED (Arrowe Park Hospital, Wirral NHS Trust) was one of the first to join the TIIG ISS and has consistently provided data since 2003/2004. The geographical location of the ED on the Wirral peninsula means that the majority of attenders (89.9% in 2009/2010) are residents of Wirral local authority, which includes some of the most and least deprived communities in England.21 Continued ED data collection and sharing has provided partners with information to develop, target and implement injury prevention activities. In this study, we analyse ED data to identify the nature of injury presentations and trends in intentional and unintentional injury presentations over a 6-year period. We then assess the contribution of ED data sharing to local violence and alcohol-related harm prevention activity.
Data quality was monitored by the ED data quality officer. Full data sharing commenced in 2003/2004, with the TIIG officer cleaning and analysing the data and providing routine reports, themed injury analyses and ad hoc data requests to partners. All partners accessing data throughout the years were asked to provide details of how they intended to use the data, its purpose and the perceived impact of data usage. In addition, local partners provided verbal feedback to the ED and the TIIG staff in ED staff meetings. Further information on data usage was obtained through partner surveys, which aimed to assess data accessibility, usage and forthcoming injury prevention priorities.

For this study, ED data covering six financial years (April 2004–March 2010) were extracted from the TIIG ISS. Variables included in the analyses were age, sex, injury group, incident location, attendance time/date, whether the patient had consumed alcohol within 3 h preceding the incident and disposal method. Injuries were categorised into intentional (i.e., violence and self-harm) and unintentional. In order to assign individuals with a measure of deprivation, their postcode of residence was mapped to a lower super output area (a geographical area [population mean=1500] used to standardise reporting of small area statistics in England and Wales) and linked to the Index of Multiple Deprivation 2007 (a composite measure of deprivation combining economic, social and housing data). Analyses examined trends in ED attendances for intentional and unintentional injury using descriptive statistics and χ² tests (including χ² for a trend). Data were analysed using SPSS V17.

RESULTS
Over the 6 years there were 242,796 ED injury attendances (accounting for 44.5% of all attendances). Most injury groups shared with TIIG are not recorded in the NCD (table 1). For example, falls are not recorded as a separate injury category in injury type.

The emergency department collects additional data on injury type (e.g., fall/burn) in a separate field to the NCD injury group field. Here, data collection methods mean that an attendance can be recorded as ‘other injury’ within the NCD injury grouping yet still be identified as a fall- or burn-related injury, for example, in the addition field. TIIG combine fields to provide partners with the most detailed and useful data on injury type, with each attendee categorised into one injury group. NCD, national commissioning dataset; TIIG, Trauma and Injury Intelligence Group.
the NCD, instead mostly being coded as ‘other injury’ or ‘medical’ attendances; the TIIG dataset identified 15910 fall-related ED attendances in 2009/2010, accounting for 17.7% of all attendances and 44.6% of injury attendances. Overall, the TIIG identified 12874 more injury attendances in 2009/2010 than the NCD. Further, 66.9% of injury attendances recorded through the NCD were categorised as ‘other injury’, accounting for one in five (17.0%) ED attendances. In comparison, 9.6% of the injury attendances recorded through TIIG were recorded as ‘other injury’, accounting for 3.8% of all ED attendances.

Table 2 shows the demography and circumstances of ED injury attendances by year. Across the 6 years, the majority (91.1%) of presentations were for unintentional injuries (eg, 44.9% fall-related, 15.8% struck by an object, 10.4% road traffic collision). Assaults accounted for 70.2% of intentional injury attendances and deliberate self-harm 29.8%; <1% were recorded as gunshot wounds or stabblings. There were significant demographic (ie, age, gender, area of residence) and circumstantial (ie, injury location, attendance time/date) differences between unintentional and intentional injury patients. For example, compared with unintentional injury, intentional injury attendances were more likely to be men (62.0%), aged 18–34 years (41.3%), live in the most deprived communities (58.8%), have been injured in a public place (58.3%) and have consumed alcohol within 3 h prior to injury (47.2%). Further, they were more likely to attend the ED at night (18:00–05:59: 63.7% cf. 54.0%; p<0.001) and at weekends (Friday–Sunday: 53.6% cf. 41.6%; p<0.001). Compared with unintentional injury attendances, a higher proportion of intentional injury attendances were admitted into hospital for further treatment/monitoring (52.2% cf. 10.7%; p<0.001).

Over the 6 years, the majority (96.4%) of injury attendances were asked if they had consumed alcohol within 3 h prior to their injury. Nearly half (47.2%) of intentional injury and 4.9% of unintentional injury patients reported drinking alcohol (p<0.001). One-third (33.0%) of alcohol-related injury attendances were recorded as an assault, 27.9% a fall and 15.6% deliberate self-harm. Alcohol-related ED attendances were more likely (p<0.001) to be men, aged 18–34 years, reside in the most deprived communities and attend the ED at night/weekends. Patients who reported having consumed alcohol prior to injury were more likely to be admitted to hospital than those who had not consumed alcohol (intentional injury: 37.5% cf. 19.7%, p<0.001; unintentional injury: 24.0% cf. 9.6%, p<0.001).

χ² for a trend analyses showed significant decreases in both intentional (35.6%; p<0.001) and unintentional (11.5%; p<0.001) injury attendances. For unintentional injuries, decreases were seen in all age groups except the 0–4 years and 65+ years age groups. For intentional injuries, all age groups decreased with the largest decreases seen in the 5–17 years (49.1%) and 65+ years (45.5%) age groups. The proportion of intentional injury attendances that were admitted to hospital decreased (5.5%; p<0.001), while the proportion of unintentional injury attendances that were admitted increased (1.3%; p<0.001). There were decreases in alcohol-related injury attendances (assaults, 30.3%; falls, 23.4%; deliberate self-harm, 56.9%). There was a decrease in the number of falls recorded as alcohol-related, compared with non-alcohol-related falls (23.4% cf. 0.8%; p<0.001).

**DISCUSSION**

This study has described the establishment of ED data sharing in a local municipality in the UK, as part of the development of a broader ISS. Injury surveillance is widely recognised to be
ED data have been used to inform the development of local multi-agency strategies for preventing violence and alcohol-related harm across the municipality, set a community safety target to reduce alcohol-related ED assault attendances by 15% (2004/2005–2007/2008), and develop, target and evaluate activities (figure 2). To facilitate data usage, bi-monthly multi-agency meetings (including TIIG, health and community safety leads) have been held during which data and interventions were discussed. Prevention activities have included enforcement work targeted at drinking establishments identified as the locations of assaults resulting in ED treatment. Such enforcement has included police and licensing officer venue visits to check compliance with UK licensing laws and provide support in preventing violence and alcohol-related harm within and around the venue. In 2007/2008, data on glass-related injury attendances were used to encourage licensed premises to use polycarbonate (plastic) glassware during peak times for violence. During 2007/2008, the ED recorded eight glass-related incidents, compared with 22 in 2006/2007. Between 2004/2005 and 2007/2008, the number of ED attendances due to alcohol-related assault declined beyond the target 15% and have decreased by 34.3% since TIIG data sharing commenced (assault data from 59 EDs in England and Wales also show reductions although to a much lesser extent). The success has largely been facilitated by strong partnership working between agencies and a commitment to use an evidenced-based approach to prevention.

It is widely acknowledged that many incidents of violence are not reported to police, yet those that result in injury can often require health treatment through an ED. The police were not aware of 25% of ED reported assault incidents. In England, increasing concerns about serious youth violence have led the government to prioritise and now mandate the collection and sharing of additional ED data on violence (ie, assault location, time and weapon). As shown in Wirral, and other areas across England and Wales, ED data can support the targeting of interventions in areas and drinking premises where violence occurs. Florence et al found that the use of ED data to inform targeted policing contributed to a reduction in violence-related hospital admissions, yet an increase in minor assaults reported by police. Our experience has identified

Emergency department attendances for assaults, alcohol-related assaults and community safety target reduction trajectory, by year.

What is already known on the subject

- Emergency department (ED) data can play a key role in developing a public health approach to injury prevention.
- The sharing of enhanced ED data to inform local violence prevention is a major government priority in the UK and elsewhere, yet many areas struggle to establish such data sharing.
- Key barriers to collecting and sharing ED data for use in injury prevention include a lack of understanding of what data can be shared and constraints with information technology.

What this study adds

- We identify how an effective ED data sharing system has been established as part of a comprehensive injury surveillance system.
- Reductions in violence were seen over the 6-year period which included the systematic integration of ED data on violence (including alcohol involvement and the nature of assault) into local violence prevention planning, activity and monitoring.
- The identification of associations between ED data sharing, multi-agency prevention activity and violence reduction support the need for more robust research to measure the specific role of ED data in violence prevention.

CONCLUSION

The establishment and use of the TIIG ISS in one municipality in England demonstrates that comprehensive data collection and sharing between EDs and multi-agency partnerships can be achieved and sustained, and can play a key role in supporting injury prevention. Focusing on intentional injuries, our study has demonstrated how additional ED data collection on alcohol and violence-related attendances, and the development of a multi-agency partnership to promote the use of ED data at a local level, has supported targeted interventions, such as policing and licensing enforcement. ED data provide vital intelligence on patient demographics that could also usefully inform broader violence prevention work towards individuals and communities most at risk. While this study shows significant reductions in intentional and alcohol-related assault attendances to the ED, further research is required to identify the specific contribution of data sharing to violence prevention.

Acknowledgements

We would like to thank Wirral University Teaching Hospital NHS Foundation Trust, particularly Christine Kennedy and reception staff working within the ED who collect the additional data, for their support and dedication. Finally we would like to thank the local Primary Care Trust and Community Safety Partnership, and staff working at the Centre for Public Health, Liverpool John Moores University, particularly Daniel Hungerford, for supporting the development and ongoing implementation of the TIIG ISS.

Funding

The Trauma and Injury Intelligence Group (TIIG) injury surveillance system (ISS) in Wirral is funded by Wirral Primary Care Trust.

Competing interests

None.
Young Australian travellers make travel insurance claims

Older Australian travellers pay higher travel insurance premiums even though it is those aged 23–30 who make the most claims mostly for damaged personal items, fractures or ligament injuries. Medical and dental claims were also high in this age group, compared with the 60–70 age group. Apparently, it is not the general health of travellers that is the issue but alcohol and mindless behaviour.

The value of universal motorcycle helmet laws

A new CDC study shows that universal helmet laws that require every motorcycle rider and passenger to wear a helmet whenever they ride increases helmet use and saves money. In 2010, cost savings in states with universal motorcycle helmet laws were nearly four times greater (per registered motorcycle) than in states without these comprehensive laws. Annual costs saved from helmet use ranged from a high of $394 million in California (which has a universal helmet law) to a low of $2.6 million in New Mexico (which has a partial law or a law requiring that only certain riders wear helmets).
