Parental perceptions regarding mandatory mouthguard use in competitive youth soccer

J M Pribble, R F Maio, G L Freed

Objective: To understand factors that influence parental perceptions regarding mandatory mouthguard use in competitive youth soccer.

Setting and subjects: A web based survey of parents whose 8–14 year old children participated in outdoor competitive youth soccer during the fall of 2002. Questions focused on: previous injury, education provided, dentist/physician recommendations, and parental perceptions of mouthguard use.

Main outcome measure: The outcome variable was parental agreement with the statement “mouthguards should be mandatory for competitive youth soccer.” Logistic regression and \( \chi^2 \) were performed using STATA 8.0.

Results: Altogether 120 parents participated. The children had a mean (SD) age of 11.8 (1.5) years and 48% were female; 14% wore mouthguards and 11% suffered orofacial injuries. Nineteen percent of parents reported receiving educational material from the youth soccer organization. Although 92% of parents believed that mouthguards were effective in reducing orofacial injuries, only one half agreed that mouthguards should be mandatory. Thirty percent of respondents reported that their dentist/physician recommended mouthguards for competitive youth soccer. Logistic regression showed that dentist/physician recommendation and parental female gender were independently associated with parental perception of mouthguard use.

Conclusions: Few athletes wear mouthguards during competitive youth soccer. Health care professionals in this study did not capitalize on the apparent influence they have on parental beliefs regarding mouthguard use. Efforts are needed by both health professionals and soccer organizations to educate parents about orofacial injuries and mouthguard use in competitive youth soccer.

METHODS

Study design and population
During the fall of 2002 we conducted a web based survey of parents of children 8–14 years of age participating in organized outdoor competitive youth soccer. The study was conducted in a Midwestern suburban community with a population of approximately 110 000. Competitive soccer was defined as a league in which players participated in a selective try-out to obtain a position on the team’s roster.

Study content and administration
After obtaining approval from both the youth soccer organization management and the institutional review board of the University of Michigan, a list of parental email addresses was obtained from the local youth soccer organization. This list was used to distribute the survey via the world wide web. Parents were sent an introductory letter that included a formal consent form along with the link to the survey. For parents with multiple children participating in

Abbreviations: AAPD, American Academy of Pediatric Dentistry; ADA, American Dental Association

www.injuryprevention.com
competitive youth soccer, the oldest child was used as the index child for this study. Parents who did not have an email address on file with the youth soccer organization or had an invalid email address were excluded from the study.

Questions were pilot tested via a personal handwritten questionnaire. One of the authors (JP) performed the pilot testing and assessed parental understanding of the questions. After pilot testing, minor changes in wording were made and the survey was developed online through a commercial survey company (Keysurvey, Stoughton, Massachusetts). The survey consisted of 34 questions. All questions, except one, allowed the participant in the survey to point and click a fixed choice answer. There was one open ended question regarding parental perceived barriers to mouthguard use in competitive youth soccer. Parental perceptions were assessed by fixed choice response statements regarding mouthguard use using a four point Likert scale. The question regarding parental beliefs about a mandatory mouthguard rule was also assessed using a four point Likert scale and dichotomized to determine percent agreement.

The survey focused on specific issues hypothesized to influence parental perceptions regarding a mandatory mouthguard rule: previous orofacial injury to index child, parent, or sibling; history of mouthguard use by parent/guardian; educational material provided by the soccer organization or coach; and health professional recommendations to use mouthguards while participating in soccer.

The definition of injury included lip laceration, tooth fracture, tooth subluxation, tooth avulsion, and tongue laceration that occurred to the competitive youth soccer athlete within the past 12 months while participating in organized soccer. Survey participants were able to click on a link that directly connected them to the online survey. After completion of the survey, data were directly downloaded onto a server. STATA 8.0 (College Station, Texas) was used for analysis.

A total of four email distributions of the world wide web survey were sent during a one month period. A final email-only version was distributed to non-respondents targeting those parents with possible suboptimal connections to the web based survey. This email survey was a shortened version of the web based survey but included all major themes.

Data analysis
Independent variables hypothesized to influence parental beliefs about a mandatory mouthguard rule were analyzed using \( \chi^2 \) statistics for association. Parental perceptions were described by dichotomizing the four point Likert scale and presenting the percentage of parents who agreed with a specific statement.

Multiple logistic regression was used to determine variables that were independently associated with parent’s agreement that mouthguards should be mandatory for competitive youth soccer. Variables that were significantly associated with parental agreement regarding mandatory mouthguard use by univariate analysis along with variables hypothesized to influence this agreement were included into the regression model. A priori variables hypothesized to influence parental beliefs regarding mandatory mouthguard use were previous injury to index child, sibling, or self (parent); gender of competitive youth soccer athlete as well as parent; education about mouthguard use; and health professional recommendations to use mouthguards while participating in soccer.

RESULTS
Of 280 potential participants, 11 were excluded due to no email address on file with the youth soccer association, and 21 were excluded due to invalid email address. Therefore, 248 parents made up our study population.

Of these 248, 48% (n = 120) returned completed usable surveys. Sixty five percent of the surveys were completed by the athlete’s female parent/guardian. Fourteen percent of parents reported that their child wore a mouthguard during competitive youth soccer participation. Table 1 demonstrates the mean age of the index athlete along with the percentage of responding parents who answered in the affirmative to the various independent variables. Univariate analysis demonstrated that dentist/physician recommendations (p = 0.008) and female gender (p = 0.008) of the responding parent were significantly associated with parental agreement about the need for a mandatory mouthguard rule in competitive youth soccer. Table 2 shows the types of orofacial injuries that were reported. Of those reporting injuries, none reported the need for acute medical/dental attention.

Fifty five percent of parents stated that their physician or dentist questioned them about their child’s athletic participation but only 30% of the parents stated that their physicians or dentists recommended mouthguard use for their child while participating in soccer.

Very few parents reported receiving any information regarding mouthguards or orofacial injuries from the soccer association. Only 19% stated that they received any information and the most common form of this information was verbally from either the coach (52%) or parent manager (29%). Parental reported barriers to mouthguard use were: discomfort (42%), peer pressure (19%), difficulty breathing (17%), and the fact that mouthguard use was not mandatory (15%).
Over 90% of parents believed that mouthguards reduce mouth and tooth injury and 86% believed that mandatory use for youth soccer would reduce injuries. Moreover, 83% agreed that making mouthguards mandatory for youth soccer would increase the likelihood that the athlete would use a mouthguard as an adolescent soccer athlete. However, only one half of the parents agreed that mouthguards should be made mandatory (table 3).

Another venue for education is the pre-participation physical examination. This encounter is explicitly designed to evaluate athletes for potential health problems that can be exacerbated by sports and to provide education on injury prevention. The pre-participation physical examination booklet states: “Asking about mouthguards may be unnecessary as they are now required in most collision sports”. However, most soccer organizations do not have mandatory mouthguard rules. To ensure the safest possible playing environment for our youth athletes, health organizations need to provide consistent and accurate information so health providers are able to inform those athletes who participate in high risk sports.

Female parents were more likely to agree that mouthguards should be mandatory for competitive youth soccer. Further analysis was done to assess other possible contributors to this finding. From our conceptual model, we felt that previous mouthguard use, previous injury, or health professional recommendations may influence the belief that mouthguards should be mandatory. However, we found no difference between male and female parents with respect to the proportion who stated that their doctor/physician recommended mouthguards, or who personally participated in youth sports. Conversely, male parents were more likely to report an orofacial injury and wear a mouthguard while participating in youth athletics than female parents. It is unclear if female parents are more cautious or more educated about orofacial injury in competitive youth soccer.

Barriers to mouthguard use reported in this study are similar to those previously reported: discomfort, peer pressure, and difficulty breathing. Most of these barriers can be addressed by the use of custom fit mouthguards. However, fitting athletes with custom mouthguards requires a visit to the dentist and can be relatively expensive (80–100 US$). Although cost was not a major barrier in our study, it may be a barrier in a different population or if parents were asked about the cost of mouthguards over their child’s playing career. Parents reported not having a mandatory mouthguard rule as a barrier to mouthguard use. The reason behind this finding is not clear. Parents may feel that peer pressure or athlete resistance to using mouthguard may be improved with compulsory use, however, further study is needed to truly understand this issue.

Most parents agreed mandatory mouthguard use reduces orofacial injury. However, only 32% of parents believed that orofacial injury is a significant problem and only 51% thought that mouthguards should be mandatory for competitive youth soccer. Put another way, parents seem to believe the risk of injury is not worth the “cost” of mouthguard use. To realize the true benefit of mouthguard use in competitive youth soccer, research efforts need to focus on understanding the incidence, economics, and morbidity of orofacial injuries in competitive youth soccer in addition to evaluating
the effectiveness of mouthguard use in competitive youth soccer.

Finally, very little educational material was provided to parents surveyed and most was verbal from the coach or other parents. Educational approaches should be developed and implemented by both youth soccer associations and health professionals. If more parents of competitive youth soccer know about orofacial injuries and their associated cost and morbidity, they may be more proactive in seeking advice from their physician or dentist.

LIMITATIONS
This study may be limited by the response rate of 48%. The response rate may have been due to the rather novel approach for this survey, the world wide web. After pilot testing, most parents stated that an email, web based survey would provide them with the most convenient method to complete this study. Almost all parents had useable email addresses. However, we did not assess the various connection speeds that parents had to the web nor the capabilities of their personal computers. Complex computer language may have caused some computers to “crash” and discourage survey completion. This is a known limitation for web based surveys and care was made to limit the survey length and graphics.23 Also, we were unable to assess the number of parents who had an email filter that eliminates email from unknown sources. The response rate may also make the findings misleading as those who did not respond may be more apathetic to mouthguard use and the issues of orofacial injury in competitive youth soccer.

Other factors that may influence injury such as playing conditions, participant behavior during competitions, and refereeing variations were not assessed during our study. Our population of athletes had to “try-out” for their position on the roster and this factor may have confounded our results making them less generalizable to other less competitive leagues. The athletes in this study and their parents may have cared less about safety and more about competition and thus may have been more aggressive. Controlling aggressive behavior of youth athletes by improved refereeing may provide significant risk reduction in this age group as these issues may contribute to increasing the incidence of orofacial injury in competitive youth soccer. More importantly, these issues may be legitimate areas for possible intervention to reduce the burden of injury in this population. Further research in these areas is encouraged.

Finally, this study was performed during one season in a specific geographical region of the country and the results may not be generalizable to other populations.

CONCLUSION
Very few competitive youth soccer athletes use mouthguards. Health professional recommendations may influence parental beliefs regarding mandatory mouthguard use. However, very few health professionals recommend mouthguards for these youth athletes. Parents seem to understand the effectiveness of mouthguards in reducing orofacial injuries but only half believe that mouthguards should be mandatory for youth soccer. Educational efforts are needed to increase the awareness of parents to the potential high cost and morbidity of orofacial injuries in youth soccer so that parents can make informed decisions regarding mouthguard use for their competitive youth athlete. In addition, health professionals need to be consistent in their recommendations and realize opportunities for simple interventions during limited interaction with this population of patients.
