**Introduction** While unintentional work-related injury is increasingly recognised as an important and preventable public health problem, population studies of the full range of work-related suicide reported to coroners have received less attention.

**Objective** To investigate the epidemiology of work-related suicide in Victoria, Australia, July 2000–December 2006

**Method** This study draws on a database of all work-related deaths reported to the Victorian Coroner, inclusive of broadly defined work-relatedness. Inclusion criteria for work-related suicide occurring between July 2000 and December 2006 were as follows:

- work stressors identified in police reports to the coroner or the coroner’s finding; or
- suicide method involved another person’s work (e.g., heavy vehicle); or
- suicide location was a workplace; or
- means of suicide was work-related; or
- deceased working for income at the time of death.

Excluded were as follows:

- cases still open for investigation;
- commuting to work;
- DIY-related.

**Results** There were 613 work-related suicides over the study period, compared with 969 unintentional work-related injury fatalities. Of the suicides, 56% directly involved work stressors; 31% jumped or lay in front of a moving train or heavy vehicle; 4% involved work agents; and 9% other. Detailed analyses of work stressor cases identified business difficulties, unemployment/redundancy, recent or previous work injury, and, infrequently, workplace bullying. The complexity of multiple contributing factors will be addressed.

**Discussion and Conclusions** Work-related suicide is a substantial problem, for which few detailed population-wide studies are available. Further research is required to understand the contribution of work stressors and effective interventions.
