Regional Reports

Southern Africa (and beyond) report

I am constantly aware that most of my reports selfishly concentrate on happenings in Southern Africa. Occasionally, I am able to glean the odd item on what is happening further north from news reports, what little there is on the internet, or from that outstanding monthly, "BBC Africa". Rather than bore readers with poor excuses for this imbalance, may I rather reconfirm that I would welcome news (in any form whatsoever) related to childhood injury in Africa, and inclusion of which would allow this column to become more representative of the entire continent than it currently is. Those who are kind enough to submit news items will be person acknowledged.

Having got that off my chest, I am thrilled to report on a fresh and exciting injury prevention campaign that has been hatched in Uganda, thanks to both support and input of the child health team of Regional Editors— I am extremely grateful to Dr Olive Kobusingye, Director of the Injury Control Centre based at Makerere Medical School in Kampala, for providing me with the following information:

"Representatives from Ethiopia, Kenya, Uganda, Zambia, Zimbabwe, South Africa, and the World Health Organization (WHO) met on December 15–17 in Entebbe, Uganda at the request of the Injury Control Centre Uganda (ICC-U) to work on a proposal for Injuries Prevention and Control in East and Southern Africa. Participants focused on the health sector issues of injury surveillance emergency medical systems, and health professional training in injury epidemiology and trauma care. A set of recommendations was formulated which has the potential to be a milestone for injury prevention in Africa.

The adoption of a standardized minimum data set for hospital based injury surveillance was discussed. A trauma registry format designed and used by the ICC-U will be presented to injury control workers in participating countries for development of a common format; it is hoped that this data set will form the core of a common trauma registry system in these countries. The single page trauma registry format includes ICD-9 categories of injury, a severity instrument (the Kampa score), victim and event information, and in-tentionality. Operate definitions for the registry have been written, and the format has already been tested in Uganda and Ethiopia. The trauma registry will be presented for use base line injury measurements while at the same time keeping the form short and simple enough for a range of health workers to fill out".

Contact details for ICC-U: Dr Olive Kobusingye, Makerere Medical School, PO Box 7072, Kampala, Uganda (fax: +256 41 530022; e-mail: olive@imul.com).

Editor’s note: While most Regional Reports have come from regular contributors—our team of Regional Editors—I am always delighted to receive contributions, regular or otherwise, from others, especially from parts of the world where we do not have Editorial Board members. Please send your contributions to the editor, Barry Pless.

Pedestrian and bicyclist safety in New York City

Pedestrian and bicyclist safety in New York City (NYC) has been in the news lately. Mayor Rudolph Giuliani has raised the ire of NYC residents by increasing the fine for jaywalking from $2 to $30, plus making a court appearance mandatory for paying fines for this offense. In addition, the mayor has recently announced that pedestrian barriers which separate pedestrians and vehicles at certain intersections will be kept up “indefinitely”. Anyone who has walked or driven the streets of New York know that its pedestrians are among the most aggressive in the world. The scene from the Midnight Cowboy in which Dustin Hoffman screams to an incensed driver, “I’m walking here!” is the attitude of the New York pedestrian, but only a little. Pedestrian and bicyclist injuries are a serious and sizeable problem in NYC city. There was a 23% increase in the number of pedestrians and bicyclists killed in motor vehicle crashes in NYC last year, from 249 in 1996 to 302 according to preliminary police statistics for 1997, 3700 hospitalizations annually, and an estimated 10 000 pedestrians struck by motor vehicles but not hospitalized. Between 1994 and 1996 pedestrian deaths due to motor vehicles declined slightly from 223 to 213. In this same period motor vehicle occupant deaths decreased more substantially from 207 to 169. Despite the preponderance of pedestrian and bicyclist deaths, a study by Transportation Alternatives, a NYC watchdog group, found that most of the $400 million of New York State and NYC funds earmarked for transportation safety in the next five years will go to improve the safety of vehicle occupants rather than the safety of pedestrians and bicyclists.

From a public health perspective, enforcement of laws as well as use of physical barriers to separate pedestrians and vehicles are perfectly respectable countermeasures against pedestrian injuries. Some of the uproar is because the least lethal players in the urban drama, the pedestrians and bicyclists, feel they are being unfairly and illogically singled out. And, of course, other measures could and should be taken, including enforcement of speed limits, use of speed bumps, creation of walking streets in heavily congested areas, and stricter licensing of taxi drivers. But the public r riduce that has been heaped on the Mayor is a reminder of the critical role played by the social context in which environmental and behavioral interventions are launched.

British green papers highlight injury prevention

In February 1998, the British government published two green papers (consultative policy statements) for England and Scotland: Our Healthier Nation and Working Together for a Healthier Scotland. These outline a strategic approach to public health build on that exist in borough setting exercises that have met with limited success.

The green papers are especially noteworthy in that the New Labour administration explicitly recognises the strong association between poverty and poor health and the need to tackle the former (as well as lifestyle and behaviour) in the context of a comprehensive health promotion strategy.

For England, 12 year targets will be set to reduce mortality and morbidity in four priority areas: heart disease and stroke, accidents, cancer, and mental health (suicide). Targets do not feature prominently (although they are not ruled out) in the Scottish paper which, in addition to the above four areas, flags up a number of others, particularly teenage pregnancy and dental health.

The green papers have been broadly welcomed by public health professionals. Disappointment has been expressed however on two main counts. First, no targets have been set to monitor progress towards reducing the widening socioeconomic inequalities in health in the UK. Second, the proposed action seems weak on specific, sustained, and adequately resourced measures designed to make a major impact on the underlying social and environmental causes of ill health. Moreover, while the poorer health (including injury) record of the Scots is acknowledged, this is not backed up by a commitment to mount a proportionately more vigorous health improvement programme north of the border.

For injury prevention professionals, the statements are a mixed blessing. On the positive side, “accidents” have held their place as priority areas in both England and Scotland. Unfortunately, the writers of the green papers have clung to an outmoded and discredited terminology, have offered virtually no new ideas to address the injury problem, and have proposed targets that are likely to be met in the absence of any further policy initiatives whatsoever. Cynics might argue that therein lies the huge political appeal of the target setting exercise!

Letters to the Editor

Safety strategies

Editor,—Jan Shield is to be commended for rallying the troops in favour of “active” safety strategies, and most of her arguments in favour of education and enforcement would undoubtedly be valid in a developed country. However I would like to offer two contrasting viewpoints on the subject which are based primarily on personal observations related to the challenges of traffic safety confronting us in a cash strapped, developing country.

Firstly, in support of passive measures is the increasing strain placed on the human and financial resources essential to conceive and sustain education programmes and law enforcement, particularly in developing countries. As such, traffic calming measures are likely to be more effective than nothing— simply because there is no acceptable solution to undisciplined traffic flow on a
Challenge of drowning prevention in low and middle income countries

EDITOR,—We read the editorial on “The challenge of drowning prevention” with great interest. There is no doubt that drowning is a major but under recognised cause of premature loss of life and disability. This has been borne out by the Global Burden of Disease Study which highlights the scale of the problem, by region and by age and sex characteristics. It is worth examining their findings further.

At a worldwide level, Murray and Lopez estimated that drowning was responsible for about half a million deaths in 1990 and ranked 20th. This leaves a substantial cause of mortality, after road traffic accidents (9th), self inflicted injuries (12th), and violence (17th) as the other injury related causes. Mortality rates from drowning were highest for children under 5 in China, followed by countries belonging to the “other Asia and islands” region, and sub-Saharan Africa, with the lowest rates in the “established market economies”. In this large group, the mortality rate ratio between China and the EME was 13:1 in boys and 22:1 in girls.

The large degree of variation between the different regions in the study must belie an even greater variation, both between and within countries, given the different geography and populations. There is great diversity in the circumstances in which drowning occurs in these different areas. Whereas swimming pools, sailing, and water sport may be priority areas in the EME, low income countries attention must be paid to drowning in streams, wells, dams, cisterns, and while fishing. Clearly there are a huge range of different environmental and behavioural circumstances. The obvious intervention to keep the child who cannot swim away from water must have a different interpretation in the different regions. Although swimming pools could be fenced in EME countries, the fencing of waterways would be impractical in countries where this runs into thousands of kilometres. This is not to say that there are no common approaches. As the editorial rightly points out, education about swimming and drowning supervision, and training in resuscitation are important first steps which could be applied globally. Researchers also need to study the circumstances under which drowning occurs and the first aid and health care response, within countries and cross nationally. Data on good practice need to be collated so that appropriate interventions which are transferable to other low and middle income countries can be easily identified. Whatever the intervention created is an urgent need to get drowning higher on the agenda for policy makers and researchers.

Injuries in less industrialised countries

EDITOR,—I read with interest the report by Mohan published in December. I agree that “Priorities for injury control have to be based on intelligent assessments of official statistics. This is what prompted me to draw attention to the improper use of the word “rate” as presented in the second paragraph, where the author writes “...the rate in India (8.6) is...” in reference to table 1 “Distribution of deaths as a percentage of regional total”.

Rates and proportions (expressed as percentages) are different. A rate is the ratio of two different quantities (generally symbolised by the equation a/b) while a proportion is the result of dividing two quantities where the numerator forms part of the denominator (symbolised by the equation a/(a + b)). A proportion multiplied by 100 is a percentage.

Rates and proportions are not synonyms. It seems to me that the author meant to say “the rate in India is 8.6” and not “rate”. This mistake could confuse those beginning in the field of epidemiology, prompting them to think that “percentage” and “rate” are synonymous terms.

BOOK REVIEW

In Target Risk, Professor Gerald Wilde of Queen’s University in Ontario, Canada assembles an impressive body of theory and evidence to support a provocative conclusion: the only effective strategy for achieving substantial and durable reductions in the rate of suffering in a population is to increase people’s desire to be safe and healthy. Traditional measures of injury prevention—engineering, education, and enforcement—are doomed to failure because they do not alter the “target levels of risk” that govern risk taking behaviors. The process of “risk homeostasis” will ultimately undermine all non-motivational countermeasures, since people will alter behaviors to achieve an equilibrium between the overall amount of risk they perceive and their overall desired level of risk.

The key to success, Wilde argues, is “expectationism”: promoting people’s interest in their future wellbeing in order to motivate adoption of smaller risk targets.
Wilde is not arguing that people enjoy or seek risk of injury. Like behavioral decision analysts and economists, he postulates that people select or accept risk targets in order to achieve other desired ends in life. When safer highways are built, drivers trade some or all of the extra safety for faster travel speeds and more relaxation (and inattention) in driving. When road conditions deteriorate (due to ice or fog), people sense elevation in risk and respond by slowing down and driving with more caution. Useful variations on this adaptation theme, Wilde challenges the effectiveness of most mainstream injury prevention measures: seat belt laws, antilock brakes, traffic lights, driver training/education, crackdowns have experienced 25% reductions in fatalities after a change in traffic law at the beginning of the year. The new laws recognize that vehicular homicide is a major city crime. Osias Baptista Neto (techtran@correo.ualcance.com.br) reported that Brazil has considerable success. 1 Lightstone AS, Peek-Asa C, Kraus JF. Relationship between driver's record and automobile. Examinations of drivers convicted of hit and run, and in one case the driver died. In six cases, the crash was reported to be charged in only one case out of 42 (2%). In all other cases (98%) the police apparently did not even issue a traffic ticket to the driver at the scene of the crash or shortly thereafter.
