Cross country variation of fractures in the childhood population. Is the origin biological or “accidental”? 

Editor,—The interesting paper by Lyons et al revealed that the annual incidence rate of fractures among children aged 0–12 years was two to three times higher in Wales than in other Western European countries. This discrepancy prompted us to briefly report on the epidemiological profile of fractures in the childhood population of Greece and discuss the implications of the observed differences.

Our data derive from the Emergency Department Injury Surveillance System (EDISS) database which is run by the Center for Research and Prevention of Injuries among the Young (CEREPRI). All types of childhood injuries treated at the emergency departments of the participating hospitals, which have well circumscribed catchment areas in urban and rural Greece, are routinely recorded in this database. The catchment area includes the Greater Athens area, where about 40% of the country’s population resides, Magnesia county in Greece mainland, and Corfu county on the island of Corfu. Our methodology was similar to that followed by Lyons et al thus allowing for reasonable comparisons.

A total of 8,557 fractures were recorded during the three-year period 1996–98 among children 0–14 years old and the estimated annual incidence rate was 12 fractures/1000 children. No significant variation was noted among children from the different sites participating in EDISS. This rate is just one third of that recorded in the Welsh childhood population. In line with what is reported by Lyons et al, and other investigators, boys were also over represented in the Greek data set (male to female ratio: 1.9) and this preponderance increased with age. Altogether 2.7% of the injured children presented with multiple fractures, a figure that is higher than that reported by Lyons et al (1.8%) and much lower than the high road traffic injury toll in Greece. In fact, one third of the multiple fracture injuries were the result of a road traffic crash, whereas traffic accidents accounted for less than 5% among injured children with only fractures.

The distribution of children by injured body part was comparable to that of the Welsh population, with fractures of radius and ulna accounting for 41% of the total, followed by fractures of fingers (3.9%), humerus (6.9%), and carpal/metacarpals (4.8%). The similarity in the pattern of fractures among children who sought emergency hospital care in the two countries can be considered as an indicator of the high quality registration system in both sites and enhances the possibility that the observed difference of the fracture incidence rate is genuine. It is worth noting, however, that despite the low overall incidence of fractures in the Greek childhood population, the proportion of skull fractures was more than twice as high as that reported in the Welsh and in a related Swedish study. Cycle helmet use may not be optimal, but according to data derived from EDISS, use of protective devices for road traffic injuries is unacceptable low, and playgrounds do not usually comply with international standards. Therefore, the underlying causes for the discrepancy in skull fracture incidence should be carefully monitored in Greece, whether it is caused by reluctance to wear helmets or otherwise, and corrective action taken.

One third of the recorded fracture injuries in both studies occurred in residential areas, where children are most of their time, followed by school areas and public premises. An average of 40% of fractures resulted from sports and leisure activities. Cultural differences and different sports and leisure time preferences between the two population groups, however, become obvious when the injuries are further analyzed by type of sport activity. Thus, ball-related injuries were dominant in our population (70% of sports related injuries among Greek compared with 40% among Welsh children), whereas wheeled sports activities were almost twice as common in Welsh compared with Greek children (35% and 20% respectively).

In conclusion, comparison of data from these studies indicate that the incidence of fractures in the Greek childhood population is similar to that observed in Sweden but much lower than that reported by Lyons and his colleagues. The question is: could this variation simply be attributed to different exposure levels and/or different prevention strategies that are followed in the respective countries, or does it reflect the expression of a biological mechanism, possibly related to nutritional factors, that accounts for fewer Greek children suffering from fractures. The latter hypothesis cannot be properly answered at this time, without careful consideration of differences in data collection, coding, and processing methods. To test this hypothesis, comparative, population-based crude and fracture specific injury incidence data from children from southern and northern European countries could be used to elucidate whether the observed differences simply reflect a corresponding difference in incidence rate or whether they are mainly related to differences in the incidence of fractures. If the latter is the case, further investigation focusing on possible differences in bone mass density or dietary intake should be considered in the interpretation of the observed variation of fractures on different population groups.

residents have rated the consultation as sufficient. Where there is good consultation there is also a high level of satisfaction with the process, and promotes walking and cycling, development of excellent public transport, and integrated land use policies for commercial and residential development.

The Scottish Needs Assessment Programme (SNAP) has recently conducted a scheme put in place. Where there is good consultation there is also a high level of satisfaction with the consultation as sufficient. Where there is good consultation there is also a high level of satisfaction with the consultation as sufficient.

Population preventable fraction of bicycle related head injuries

Editor,—The article by Dr Kopjar in a recent issue of the journal discussing the use of the population preventable fraction concerning bicycle related head injuries and helmet use was very interesting. Dr Kopjar uses the odds ratio (OR), obtained from case-control studies, as a measure of association. The odds ratio in a case-control study is how we view the odds of disease (cases/non-cases) and the risk of disease (cases/total) are approximately equal (keeping in mind that the odds of disease is not available from a case-control study, only the OR).

The OR would then be an unbiased estimate of the incidence rate ratio, with no rare disease assumption. Dr Kopjar states that “Incidence of head injuries is low, suggesting that the incidence will be small and can be used as a valid proxy for the RR”. This point deserves further comment. There are two distinct types of case-control studies: the incidence density type and the cumulative incidence type. We may assume an underlying cohort for each type from which cases and controls are sampled. The primary difference between the incidence density and cumulative incidence case-control studies is how we view the cohort and what information the control group provides. The incidence density case-control study views the underlying cohort as being stable and dynamic. The control group in an incidence density case-control study is intended to provide an estimate of the fraction of population time exposed and unexposed. The OR, then, is a ratio of pseudo-rates and provides an unbiased estimate of the incidence rate ratio, with no rare disease assumption (table 1). Thus it does not matter whether the disease is rare, only that controls be selected independently of exposure status to be representative of the distribution of the exposure in the source population which produced the cases.

The cumulative incidence case-control study is where the rare disease assumption is important. The cohort underlying the cumulative incidence case-control study should be thought of as closed and fixed. Incident cases are sampled throughout a defined time period and controls are residual non-cases (that is, those individuals at risk who did not become cases over this period). In this situation, the control group does not provide a representation of person time. Instead, the relationship between the odds and the risk is what is key. That is, when the disease is rare, the odds of disease (cases/non-cases) and the risk of disease (cases/total) are approximately equal (keeping in mind that the odds of disease is not available from a case-control study, only the OR).

Risk = 10 cases/100 total at risk/10 cases/(100 total non-cases) = 10 cases/990 non-cases = odds

The case-control studies that provide the OR estimates used in Dr Kopjar’s article could be seen as the incidence density type. The OR would then be an unbiased estimate of the incidence rate ratio, with no rare disease assumption.

BOOK REVIEW

This book is an important contribution to the field of accident and injury research. It is a book for newcomers to qualitative research and as such would be an excellent key text for teaching. The book outlines a range of qualitative research methods and builds this into an appreciation of the theoretical underpinnings that favour one method more than another. Beyond pure methods and theory, the book conveys the realities of planning, undertaking, and finishing a research project.

The initial chapter “injury and the disclosure of the truth” is particularly compelling as it guides us into the minds of those who engage in qualitative research; those seeking “the insider perspective on injury” (p xviii). For qualitative researchers there is “no ultimate truth” (p xix) but a series of constructed relationships grounded in cultural and social phenomena.

Impressively, it addresses the issue of analyzing and writing up the research—an area often ignored in methodological texts. We are given the opportunity to look over a raw transcript and to see how it is analyzed and how to present these data after analysis.

Where the book could be stronger is in the decision to cover many methods briefly, as opposed to a few methods in greater detail. This trade off can be forgiven as it is an introductory book and contains suggestions for further reading about each method.

The inclusion of certain methods, or what Rothe calls “data collection plans”, seems rather idiosyncratic—new to me were such things as “walk and talk” and the use of public meetings. This section could be better ordered to promote the actual methods rather than differences in the field location and grouping of participants. It would contest his belief that content analysis can be qualitative as I cannot see how counting can be anything other than quantitative—regardless of what you are counting.

The insights into fieldwork experience are invaluable (chapter 7). Often methods books offer a systematic overview without furnishing us with insights into the actual hands-on process of conducting research. Similarly the chapter on ethics, brief as it is, is an important inclusion as it is a key consideration of any research project—but particularly so with the degree of personal contact with respondents one often gets when conducting qualitative research.

Minor quibbles with the book are that it has no index; an omission diminished by the excellent glossary and appendices. Frustratingly, the bibliography is a selection of books rather than all of those referred to in the text. As a newcomer to the field, I was surprised at the dearth of qualitative research conveyed in papers at the 5th World Conference on Injury Prevention and Control (Delhi, 2000). This book hopefully marks a new era in
attended a satellite meeting of the Society organised by our enthusiastic Asian representative. We are confident that the international organising committee for the next conference in Montreal in 2002 will be as keen as we are to continue the tradition and ensure a strong ISCAIP presence on that occasion also.

Perhaps I should try to spell out my own hopes and aspirations for ISCAIP. Our foremost strength lies in our potential to foster collaboration and I believe we should seek, through both electronic and conventional means, to develop this role further. Second, the membership of the Society represents an unsurpassed critical mass of expertise and (to use an old fashioned phrase) sapiential authority. Let’s use our collective clout to maximise the effectiveness of injury prevention policies and practices in every corner of the globe through the dissemination of research based evidence and guidelines. Finally, the Delhi conference brought home to me (and I’m sure many others) just how dramatically different are the circumstances and obstacles faced by injury prevention professionals in India and other developing countries compared with the US, Europe, or Australia. Most ISCAIP members are all to well aware of this, of course, yet how many of us have found ways of coping constructively with the impediments? Dinesh Mohan has called for the institution of imaginative collaborative projects between researchers working in low income countries (containing most of the world’s population) and high income countries. Are injury prevention professionals ready to respond to this challenge? If so, how? Should we seek additional resources to oil the wheels of such ‘north-south’ collaboration and, if so, where will we find them? I appeal to all readers of Injury Prevention to reflect on these questions and to try to articulate some answers. I can think of no more urgent task for ISCAIP—or indeed for the injury prevention community as a whole—in the 21st century.

D H STONE
Chair, ISCAIP,

From the Chair of ISCAIP

As many readers will be aware, the elections for the new ISCAIP Board were held in 2000. I feel deeply honoured to have been elected Chair and wish to thank all concerned for their support. My colleagues on the Board are an outstanding team of highly respected injury prevention professionals and I am confident that we, together with the membership, can take ISCAIP into the new century with a renewed sense of purpose and urgency.

I want especially to record my appreciation of the incalculable contribution of Fred Rivara, founding Chair of ISCAIP, in laying the foundations of the Organisation and in presiding over a smooth transition to the new regime. Fred’s leadership has been truly inspirational and unlikely to be equalled in the foreseeable future. I am delighted to report that Fred has agreed to participate in ISCAIP Board discussions in his capacity as Immediate Past Chair and we look forward to his continuing involvement with the Society.

Since taking up the position, I have embarked on a steep learning curve. In the short life, ISCAIP has built up an impressive database of personal values and the social and cultural structure” (Moller quoted in Rothe, 1998). CALENDAR

10th Annual Conference on International Safe Communities
21–23 May 2001, Anchorage, Alaska, USA. The theme is ‘Safe Work, Safe Play Around the Clock. Further information and online registration: www.alaska-ipc.org or from Conference Manager, Diana Hudson, The Alaska Injury Prevention Center, PO Box 210736, Anchorage, Alaska, USA 99521-0736 (tel: +1 907 929 3939, fax: +1 907 929 3940, email: diana_hudson@hotmail.com).

International Child Passenger Safety Technical Conference
2–6 June 2001, Indianapolis, Indiana, USA. This conference will offer workshops on child passenger safety certification, boosters and belts for school age kids, legislation and advocacy, model law enforcement programs, restraint programs for children with special needs, transportation in other vehicles, and more. Professionals and volunteers from the field of transportation, engineering, public health, education, medical services, and insurance are invited to attend. Further information: International Center for Injury Prevention, www.cipsafe.org.

DETR Good Practice Conference
20–22 June 2001, Bristol, UK. The DETR, the UK government department with responsibility for road safety, is staging this conference to disseminate good practice in road safety engineering and speed management, and to launch their good practice guidelines. Further information: Kevin Clinton, RoSPA, Road Safety Dept, Edgbaston Park, 353 Bristol Road, Birmingham B5 7ST, UK (tel: +44 (0)121 248 2125, fax: +44(0)121 248 2001).

Nordic Safe Communities Conference
21–24 August 2001, Denmark. Further information: Moa Sundeström, Karolinska Institutet, Department of Public Health Sciences, Division of Social Medicine, Norrbacks, SE-171 76 Stockholm, Sweden (tel: +46 8 517 77948, fax: +46 8 334693, email: moa.sundstrom@socmed.sll.se).

4th International PhD Course on Safety Promotion Research
17–29 October 2001, Stockholm. A course for researchers and PhD students in public health sciences and those interested in injury prevention and safety promotion research. Further information: Moa Sundeström, Karolinska Institutet, Department of Public Health Sciences, Division of Social Medicine, Norrköpings, SE-171 76 Stockholm, Sweden (tel: +46 8 517 77948, fax: +46 8 334693, email: moa.sundstrom@socmed.sll.se, web site: www.ki.se/psyh educación).

1st International Course on the Global Burden of Injury
30 October–3 November 2001, Stockholm. The aim of the course is to provide a general scientific platform for the understanding of global trends and international differences in injury mortality and morbidity; for PhD and postgraduate students and senior researchers. Further information: Moa Sundстрём, Karolinska Institutet, Department of Public Health Sciences, Division of Social Medicine, Norrköpings, SE-171 76 Stockholm, Sweden (tel: +46 8 517 77948, fax: +46 8 334693, email: moa.sundstrom@socmed.sll.se, web site: www.ki.se/research/courses/postgrad_catalogue/fall2000_en.html).

6th World Conference on Injury Prevention and Control
